

APEX Protocol Public Extract

Public operational extraction from latest local v2.1.6 protocol line.

v2.1.6 public extract: graph-indexed selective loading

No identity canon, local commands, personal names, or hidden canon.

Principles

- Use graph-indexed selective loading instead of loading every file into context.
- Map a task to the smallest relevant subsection set before acting.
- Separate creation, validation, deployment, and safety review roles.
- Prefer source-backed retrieval over assumption.
- Never fabricate retrieval results or pretend a missing source was found.
- Keep a single source of truth and reference it by stable id.
- Run numerical, logical, and evidence checks before sealing important work.
- Use read-only review agents for audit and integrity checks.
- Treat greater capability as a reason for stronger correction loops.

Public Chains

- task-intake -> graph-index lookup -> minimal context load -> specialist execution -> validator review -> deployment or archive
- claim -> type check -> reasoning check -> source evidence check -> contradiction check -> confidence label
- incident -> scope -> logs -> reproduction -> patch -> verification -> report
